

# Practical Applications for Risk Quantification

By Varunee Pridanonda / Richard Wilkins, PricewaterhouseCoopers

28 November 2005

\*connectedthinking

PRICEWATERHOUSECOOPERS 

# Agenda

- Why move beyond qualitative risk management ?
- Data characteristics and core risk quantification techniques
- Case studies: applications of risk quantification
- Live Monte Carlo simulation
- Integrating risk quantification into existing risk management and decision making processes

# Why move beyond qualitative risk management ?

---

\*connectedthinking

PRICEWATERHOUSECOOPERS 

## Risk quantification is not new

- Doctors / pharmaceutical
  - risks tolerance and drug trials
- Treasurers
  - volatility of investment returns (Value at Risk)
- Corporate planning
  - “what if” sensitivity analysis, scenario planning
- Bank credit departments
  - risk return optimisation
- Feasibility studies
  - real option analysis
- Engineering design
  - safety, reliability, risk tolerance
- Insurers
  - price of risk reflected in premium; likelihood of claims
- Environment
  - regulation of emissions
- Weather
  - predictive reliability, global warming
- M&A
  - uncertainty as a basis of negotiation
- Options evaluation
  - boundaries of acceptable risk
- Decision making
  - risk analysis in exit strategies; cost benefit analysis

.....

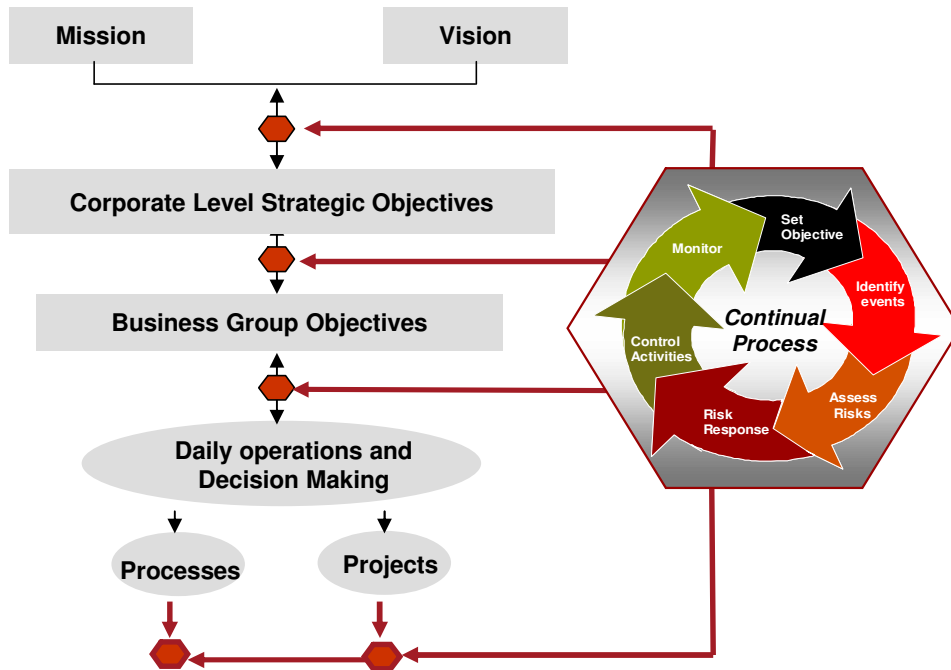

## Risk quantification is performed for many reasons ...

- To better understand one or more risks
- Source of competitive advantage – to allow more, well managed risk to be taken
- To make ‘risk adjusted’ decisions – particularly with large capital projects
- To better understand extreme events
- To measure cost / benefit of managing highest risks
- Calculate expected annual loss due to risk
- To be objective, transparent and rational
- To check on or manage expectation and perception (check on counter-intuitive risk)
- To establish risk appetite and tolerance
- To establish risk-based capital

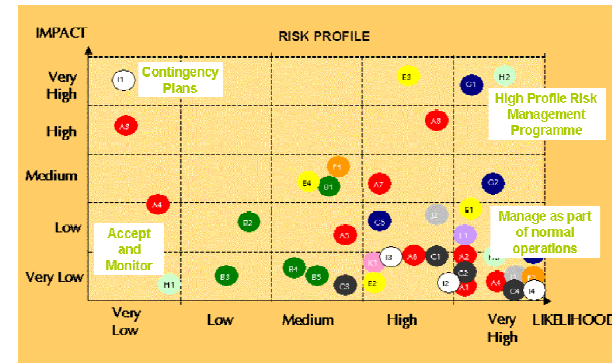

.....when qualitative analysis is not enough

Enterprise risk management promotes building risk principles into key operating and decision making processes – most start with a qualitative approach

**Risk assessment process is embedded into core processes and decision making activities**

**5x5 qualitative risk map**

**Risk matrix or risk register**

Objective: Increase market share of new product by 15% by Q4 2004 For illustration purposes only

Risk	Risk Strategy	Risk Response	Residual Risk		Action Plan	Target Completion Date	Risk Owner
			Likelihood	Impact			
Detailed description of risk	Description of risk response	Description of existing response to risk	Likelihood rating from 1-5	Impact rating from 1-5	Action plan to mitigate risk to an acceptable level	Target completion date	Name of persons who are the risk owners
Organisation has insufficient staff to provide adequate customer service	Reduce	<ul style="list-style-type: none"> <li>Establish manpower allocation policy</li> <li>Establish appropriate human resource policy</li> </ul>	3	2	<ul style="list-style-type: none"> <li>Implement the new manpower allocation policy</li> <li>Conduct training to education roles and responsibilities</li> <li>Prepare HR development plan</li> </ul>	Q3 2004	<ul style="list-style-type: none"> <li>Planning Dept</li> <li>Human Resources Dept</li> </ul>

# Data characteristics and core risk quantification techniques

PRICEWATERHOUSECOOPERS 

# Understanding data - *frequency* (or likelihood) of events is measured in terms of units per period of time or per unit of something else

## Frequency

## Examples

## Features

### High

Occurs hundreds, thousands or millions of times

- Credit defaults per year in a large bank
- Car accidents per year for taxi company
- Cable cuts for a power company per year
- Letters lost in the post per year

- Lot of data but sometimes hard to collect
- Statistically significant 'volume' of data

### Medium

Occurs few times per year to once every 2 or 3 years

- Aircraft in near miss per year at major airport
- Loss or gain of a key account per year
- Major component failure in a factory per year

- Data often not collected
- Reliant on record of investigations, memory or experience elsewhere
- Statistically significant conclusions rare
- Greater uncertainty

### Low

Occurs from once every few years to once in 100,000 years or more

- Dam failure - 20 times over past 100 years
- Nuclear power station melt down - two times in 50 years globally
- Project delayed 10 weeks due to late supplier delivery leads to loss of key customers

- Little data
- Quantitative estimates based on experience of specialists, consensus in workshop, exploration of scenarios
- Modelling limited to exploring possibilities

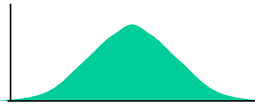

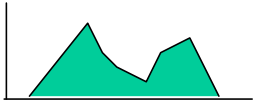

# Understanding data – there are alternative ways of expressing the loss or gain (*impact*) with increasing sophistication ....

- Point estimate                      10 lives, \$1m, 40 trees, 5 customers
- Estimate plus contingency        \$100k +10%
- Range                                  NPV of project:  
   Optimistic = + \$30m  
   Expected = + \$10m  
   Pessimistic = - \$20m
- Distributions                        Capture complex uncertainty

increasing  
sophistication

# Characterising uncertainty with distributions

Name of distribution	Example of distribution	Defining characteristics	Use	Situations where suitable
Triangular		<p><i>Minimum, most probable, maximum</i></p> <p>Continuous, bounded</p>	<p>Most commonly used distribution with no theoretical justification but simple and clear to use. It overestimates the size of tails at the expense of values close to the mean</p>	<p>Where distribution is not known and thought not to be a normal distribution because it is <i>bounded</i> or not symmetrical. Situations where a simple intuitive understanding is paramount and flexibility is a great advantage</p>
Normal		<p><i>Mean, variance</i></p> <p>Parametric, continuous, differentiable, unbounded</p>	<p>Frequently used distribution due in part to the central limit theorem which states that the mean of a set of values drawn independently from the same distribution will be normally described</p>	<p>...</p>
Uniform distribution		<p><i>Maximum, minimum</i></p> <p>Continuous, not differentiable, bounded</p>	<p>Used if the variable is bounded by a known maximum and minimum, and all values in between occur with equal likelihood</p>	<p>+ many others</p> <ul style="list-style-type: none"> <li>• Binomial</li> <li>• Poisson distribution</li> <li>• Exponential</li> <li>• Log normal</li> <li>• Beta distribution</li> <li>• Weibull</li> <li>• StudentT</li> <li>• Pareto</li> <li>• etc</li> </ul>
General probability distribution		<p>Continuous, not differentiable, bounded</p>	<p>Often used to represent subjective opinions of experts, particularly when formed using pairwise comparison</p>	

# Special attention must be taken not to confuse the user with the language associated with statistics

Name of statistic	Definition	Use	Dangers												
<p>Mean (expected value)</p>	<p>Average of all generated outputs</p>	<p>Very useful and one of the most common statistics reported. Eg the average NPV of a transaction. It also has the property that if 2 or more variables are independent, then:</p> <p>Mean (a+b) = mean(a) + mean(b), and</p> <p>Mean (a*b) = mean (a) * mean (b)</p>	<p>Confusing the mean with the most probable (mode)</p>												
<ul style="list-style-type: none"> <li>• Standard deviation</li> <li>• Variance</li> <li>• Median</li> <li>• Value at risk</li> <li>• Percentiles</li> <li>• Expected loss</li> <li>• Unexpected loss</li> <li>• Skewness</li> <li>• Kurtosis etc</li> </ul>		<table border="1"> <thead> <tr> <th data-bbox="831 815 904 1002"></th> <th data-bbox="904 815 1223 1002">Classification of distribution</th> <th data-bbox="1223 815 1854 1002">Brief description</th> </tr> </thead> <tbody> <tr> <td data-bbox="831 1002 904 1161">1</td> <td data-bbox="904 1002 1223 1161"> <ul style="list-style-type: none"> <li>• Continuous</li> <li>• Discrete</li> </ul> </td> <td data-bbox="1223 1002 1854 1161"> <p>Smooth profile in which any value within the limits can occur</p> <p>Variable can only represent discrete values eg number of warehouses</p> </td> </tr> <tr> <td data-bbox="831 1161 904 1350">2</td> <td data-bbox="904 1161 1223 1350"> <ul style="list-style-type: none"> <li>• Bounded</li> <li>• Unbounded</li> </ul> </td> <td data-bbox="1223 1161 1854 1350"> <p>Limited to possible values</p> <p>Extends from minus infinity and/or plus infinity eg normal distributions</p> </td> </tr> <tr> <td data-bbox="831 1350 904 1361">3</td> <td data-bbox="904 1350 1223 1361"> <ul style="list-style-type: none"> <li>• Parametric</li> <li>• Non-parametric</li> </ul> </td> <td data-bbox="1223 1350 1854 1361"> <p>Theoretically derived distribution after making assumptions about the nature of the process that is being modelled eg exponential distribution</p> <p>Distributions that are artificially created eg triangular distributions</p> </td> </tr> </tbody> </table>		Classification of distribution	Brief description	1	<ul style="list-style-type: none"> <li>• Continuous</li> <li>• Discrete</li> </ul>	<p>Smooth profile in which any value within the limits can occur</p> <p>Variable can only represent discrete values eg number of warehouses</p>	2	<ul style="list-style-type: none"> <li>• Bounded</li> <li>• Unbounded</li> </ul>	<p>Limited to possible values</p> <p>Extends from minus infinity and/or plus infinity eg normal distributions</p>	3	<ul style="list-style-type: none"> <li>• Parametric</li> <li>• Non-parametric</li> </ul>	<p>Theoretically derived distribution after making assumptions about the nature of the process that is being modelled eg exponential distribution</p> <p>Distributions that are artificially created eg triangular distributions</p>	
	Classification of distribution	Brief description													
1	<ul style="list-style-type: none"> <li>• Continuous</li> <li>• Discrete</li> </ul>	<p>Smooth profile in which any value within the limits can occur</p> <p>Variable can only represent discrete values eg number of warehouses</p>													
2	<ul style="list-style-type: none"> <li>• Bounded</li> <li>• Unbounded</li> </ul>	<p>Limited to possible values</p> <p>Extends from minus infinity and/or plus infinity eg normal distributions</p>													
3	<ul style="list-style-type: none"> <li>• Parametric</li> <li>• Non-parametric</li> </ul>	<p>Theoretically derived distribution after making assumptions about the nature of the process that is being modelled eg exponential distribution</p> <p>Distributions that are artificially created eg triangular distributions</p>													

## Examples of alternative risk quantification techniques

	<b>Top-down</b>	<b>Bottom-up</b>
<b>Non-probabilistic</b>	<ul style="list-style-type: none"><li>• Scenario analysis</li></ul>	<ul style="list-style-type: none"><li>• Stress test</li><li>• Sensitivity analysis</li></ul>
<b>Probabilistic</b>	<ul style="list-style-type: none"><li>• Stock factor models</li><li>• Income-based models (Earnings at Risk)</li></ul>	<ul style="list-style-type: none"><li>• Asset liability models</li><li>• Market factor models (Value at Risk)</li><li>• Actuarial models</li><li>• Causal models (event trees, fault trees, event simulation)</li></ul>

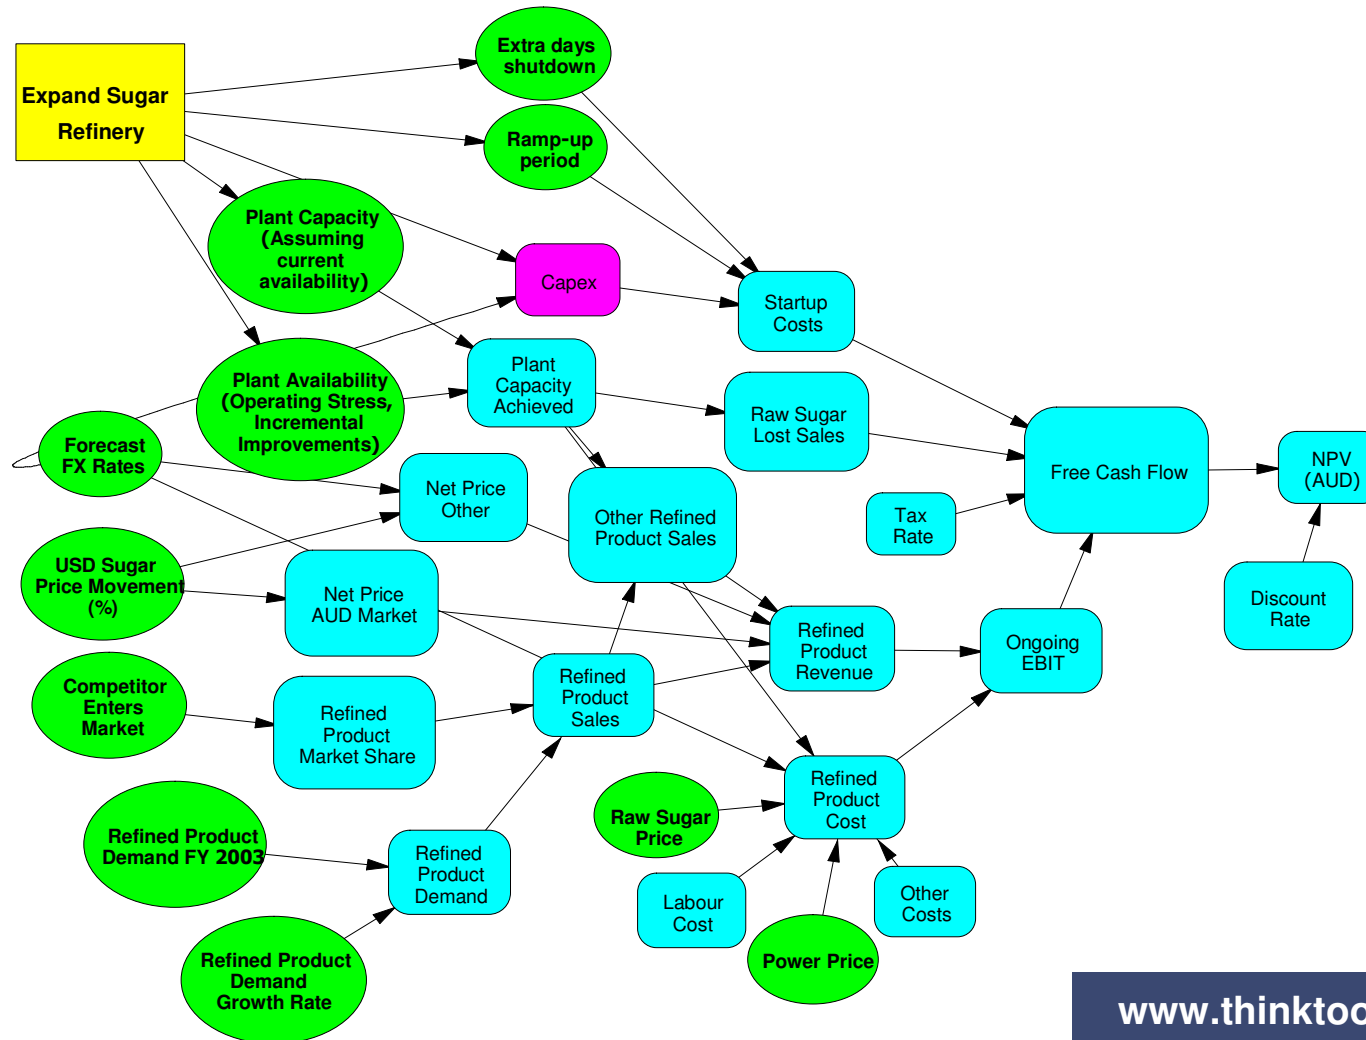

Sensitivity analysis examines effect of different assumptions such as changed parameters or different distributions on an outcome.

- “What if... ?” analysis
- What is the impact on our sales revenues if the Thai baht deteriorates by 10% against the US dollar ?
- In the context of a project, sensitivity analysis may examine how responsive a project’s Net Present Value (NPV) and Internal Rate of Return (IRR) is to a change in an input.

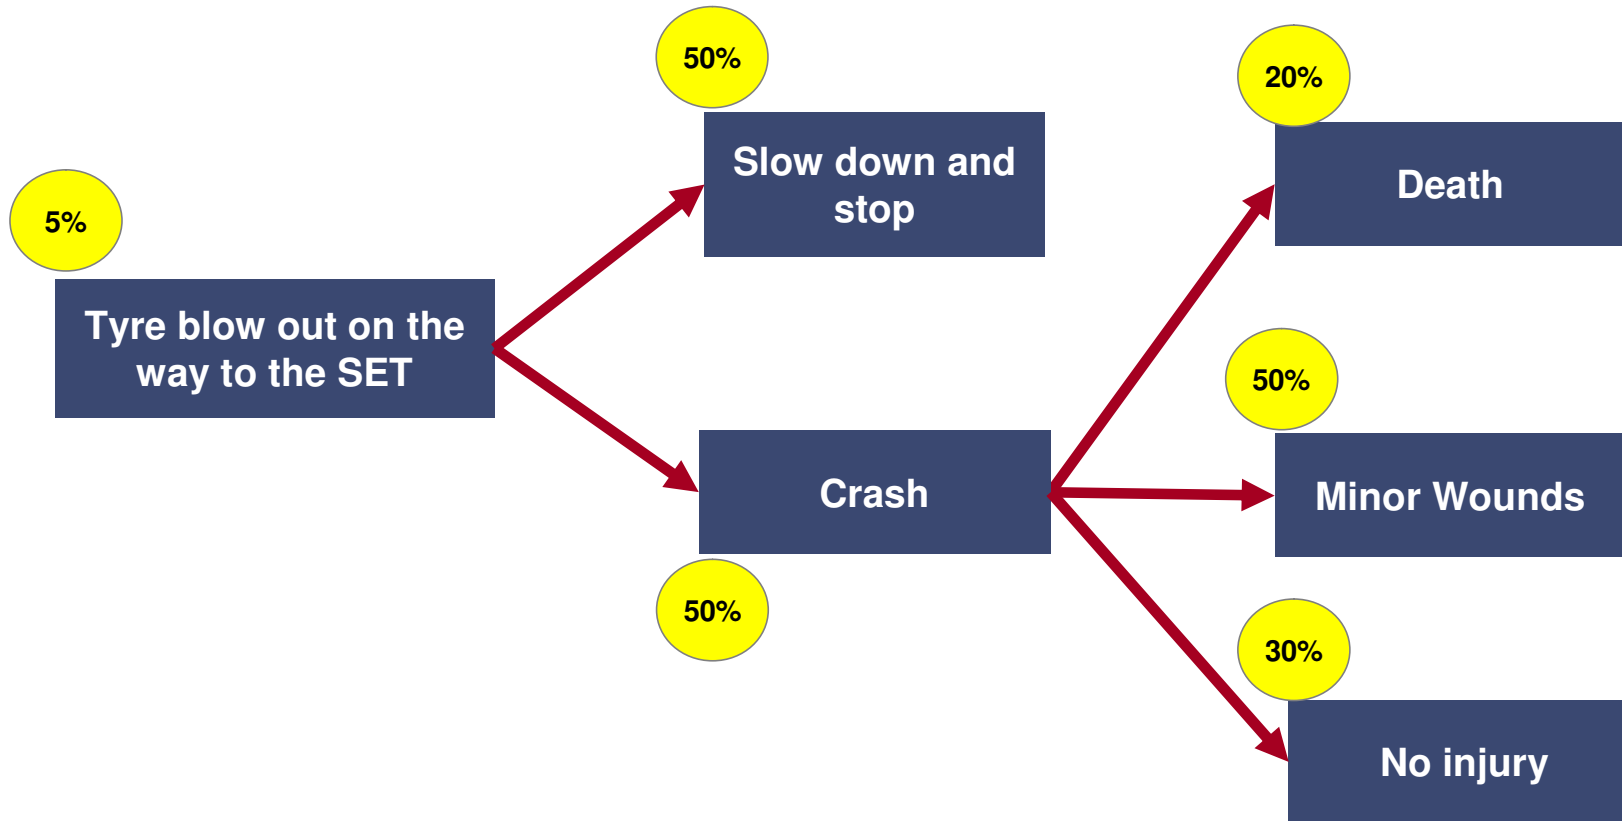

# Scenario analysis - different scenarios describe a particular combination of internally consistent events that may occur in the future

Influence diagrams are about mapping out the context for the risk at an appropriate level of detail

# Event tree analysis

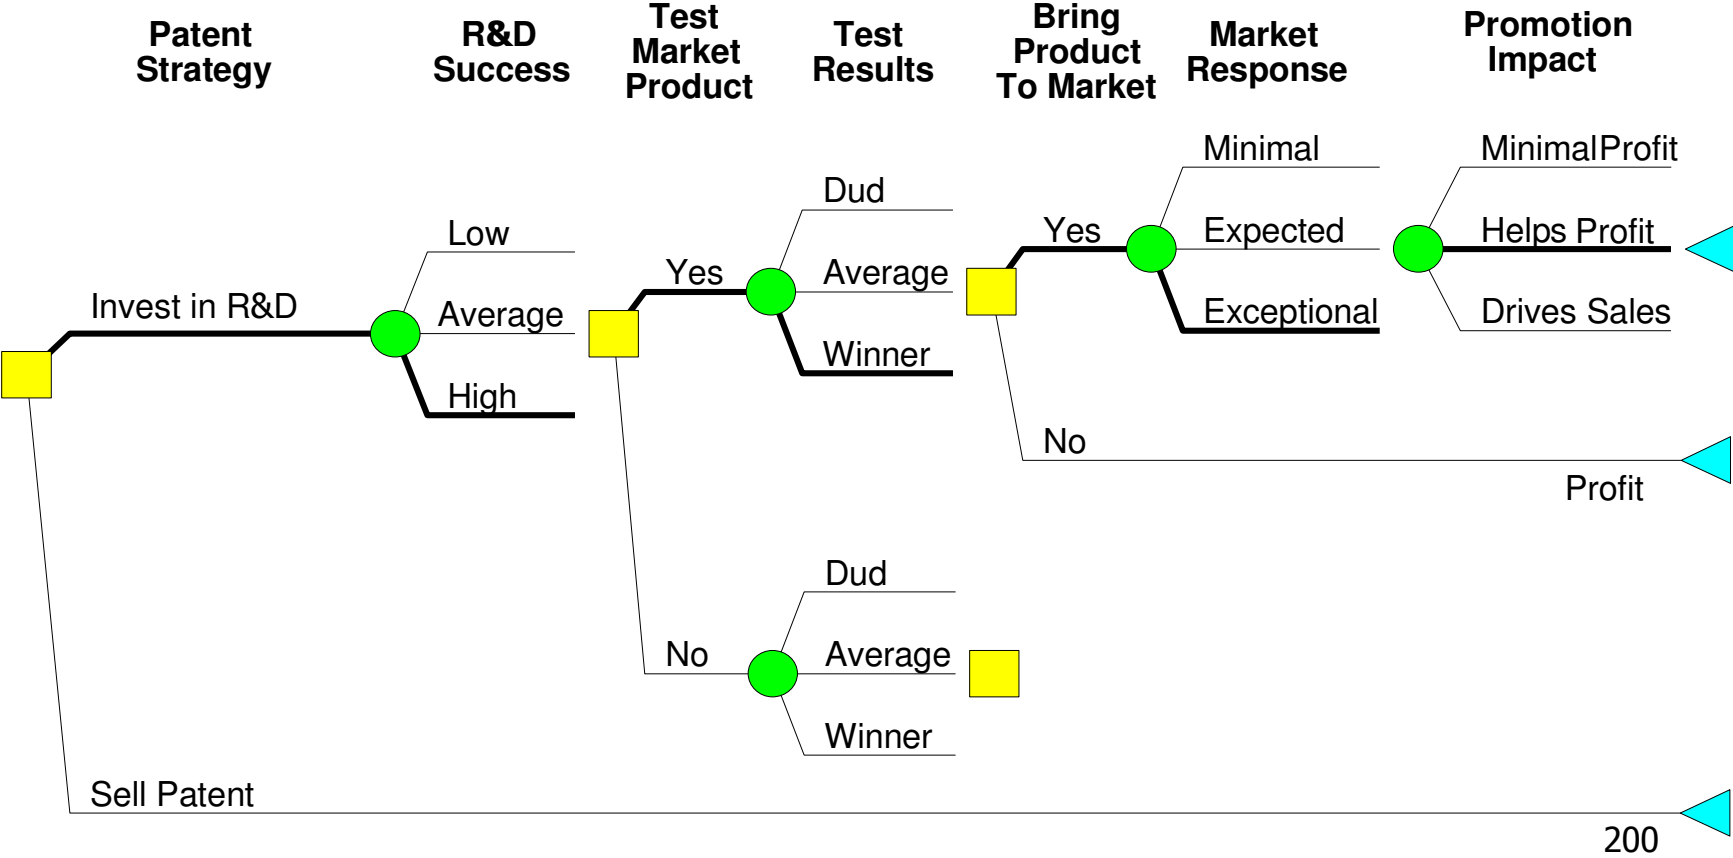

**Chance of dying due to a crash following a blow out on the way to the SET is ...**

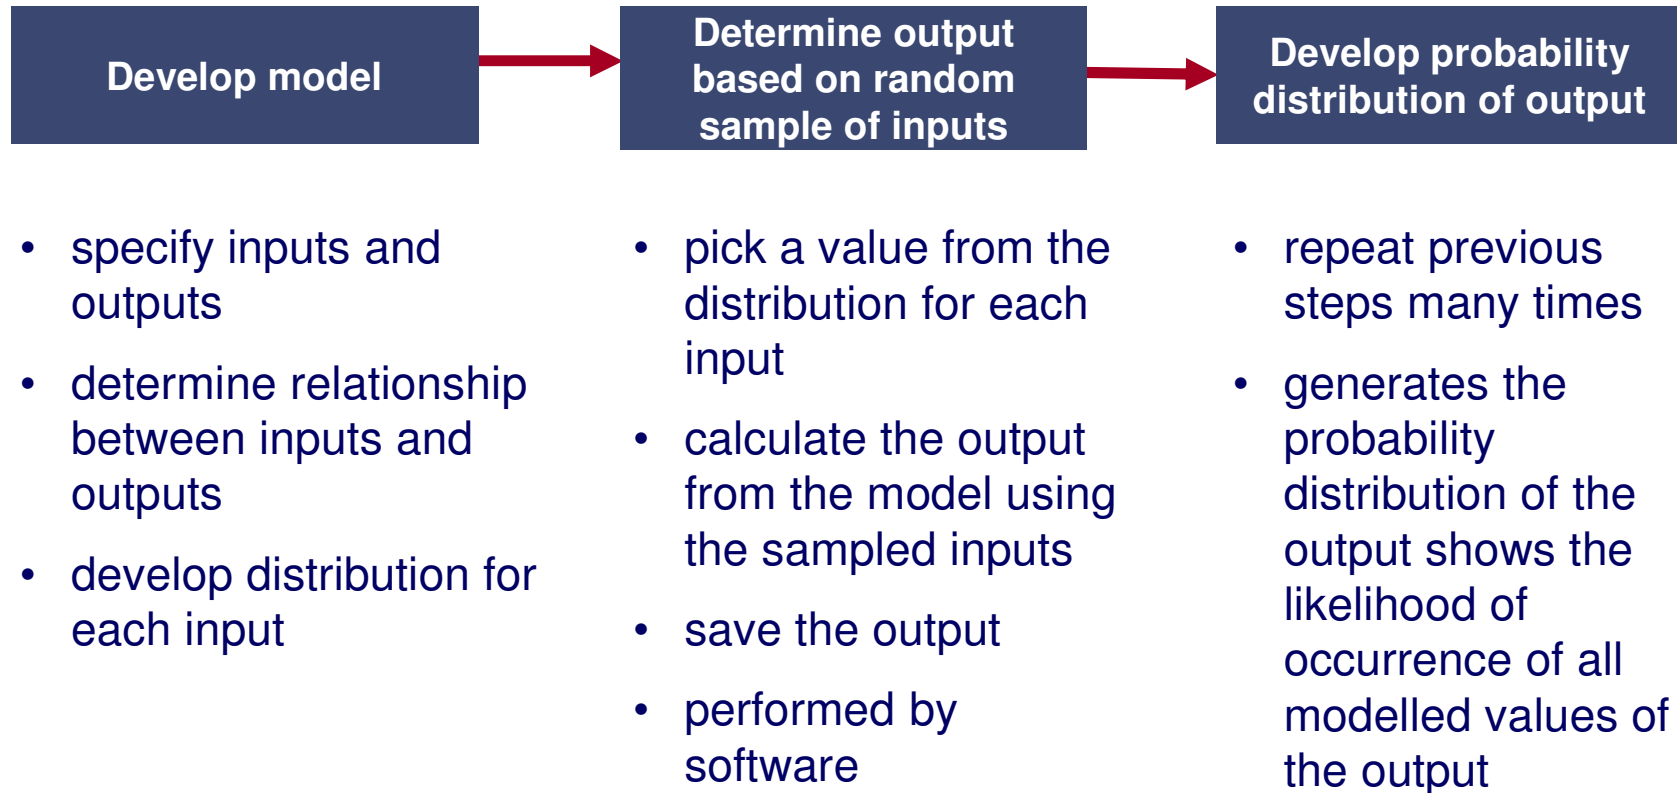

**0.5% or 1:200**

# Risk identification and analysis should combine objectivity, logic and quantification

# Simulating potential losses using techniques such as monte carlo analysis

A banking example –  
 How much capital does a bank require to cover possible losses from credit defaults ?

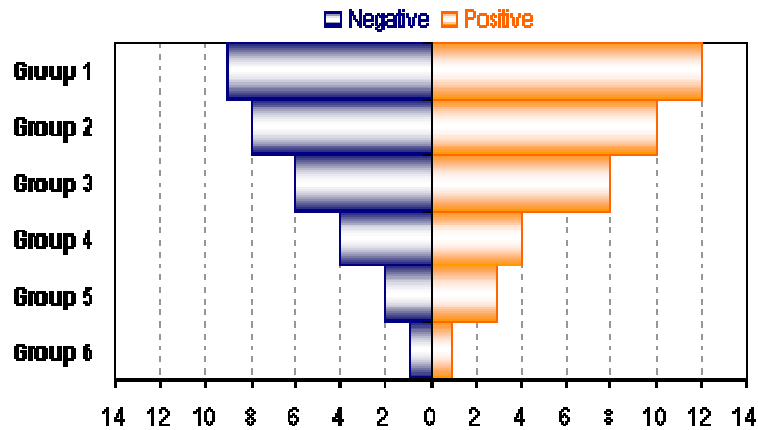

# Sample outputs

- Cumulative frequency chart

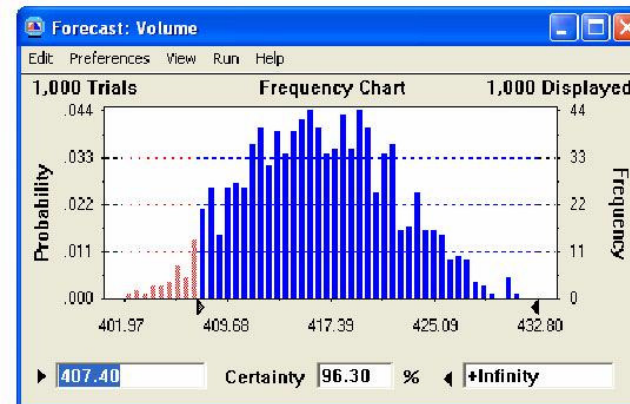

- Tornado chart

- Scatter diagram

- Histogram

# Tornado chart - understand the risk sensitivities

**Net Present Value is sensitive to capacity, availability, demand and prices**

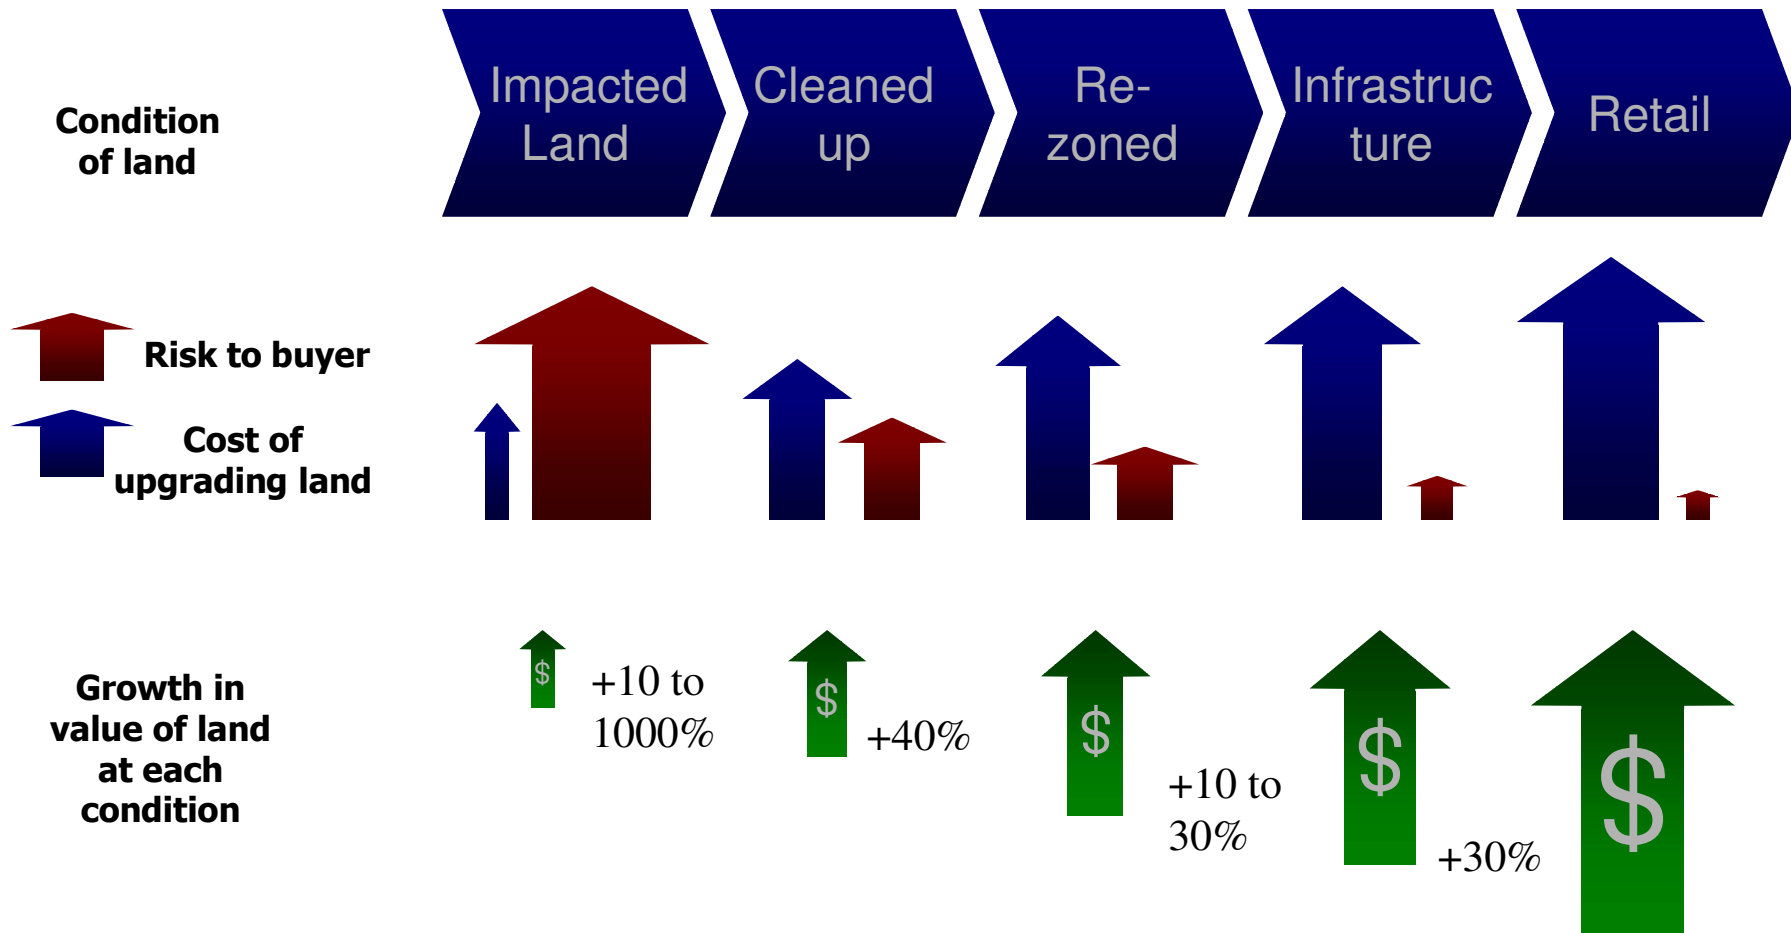

Case studies:  
Applications of risk  
quantification

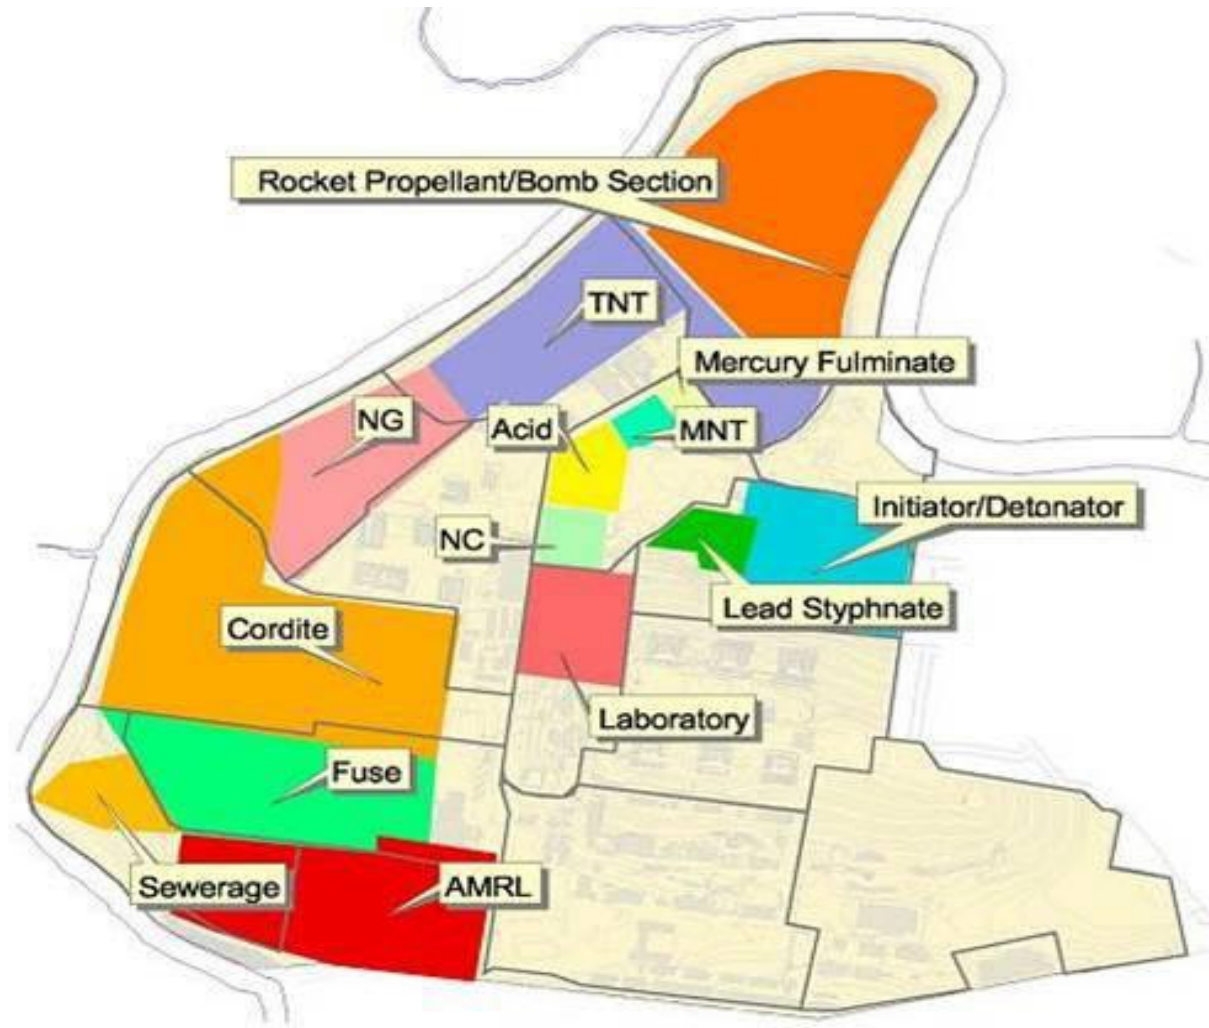

---

# Case Study 1 – Value of uncertainty analysis

How much should the seller of 15 contaminated land plots spend to increase the value of the land ?

# Case Study 1 – Value of uncertainty analysis

# Case Study 1 – Value of uncertainty analysis

Estimates of Soil Remediation Costs by Area - February Estimate

- 95% Confidence level (A high but plausible final cost)
- 80% Confidence limit (A reasonable budgetary/planning cost)

# Case Study 1 – Value of uncertainty analysis

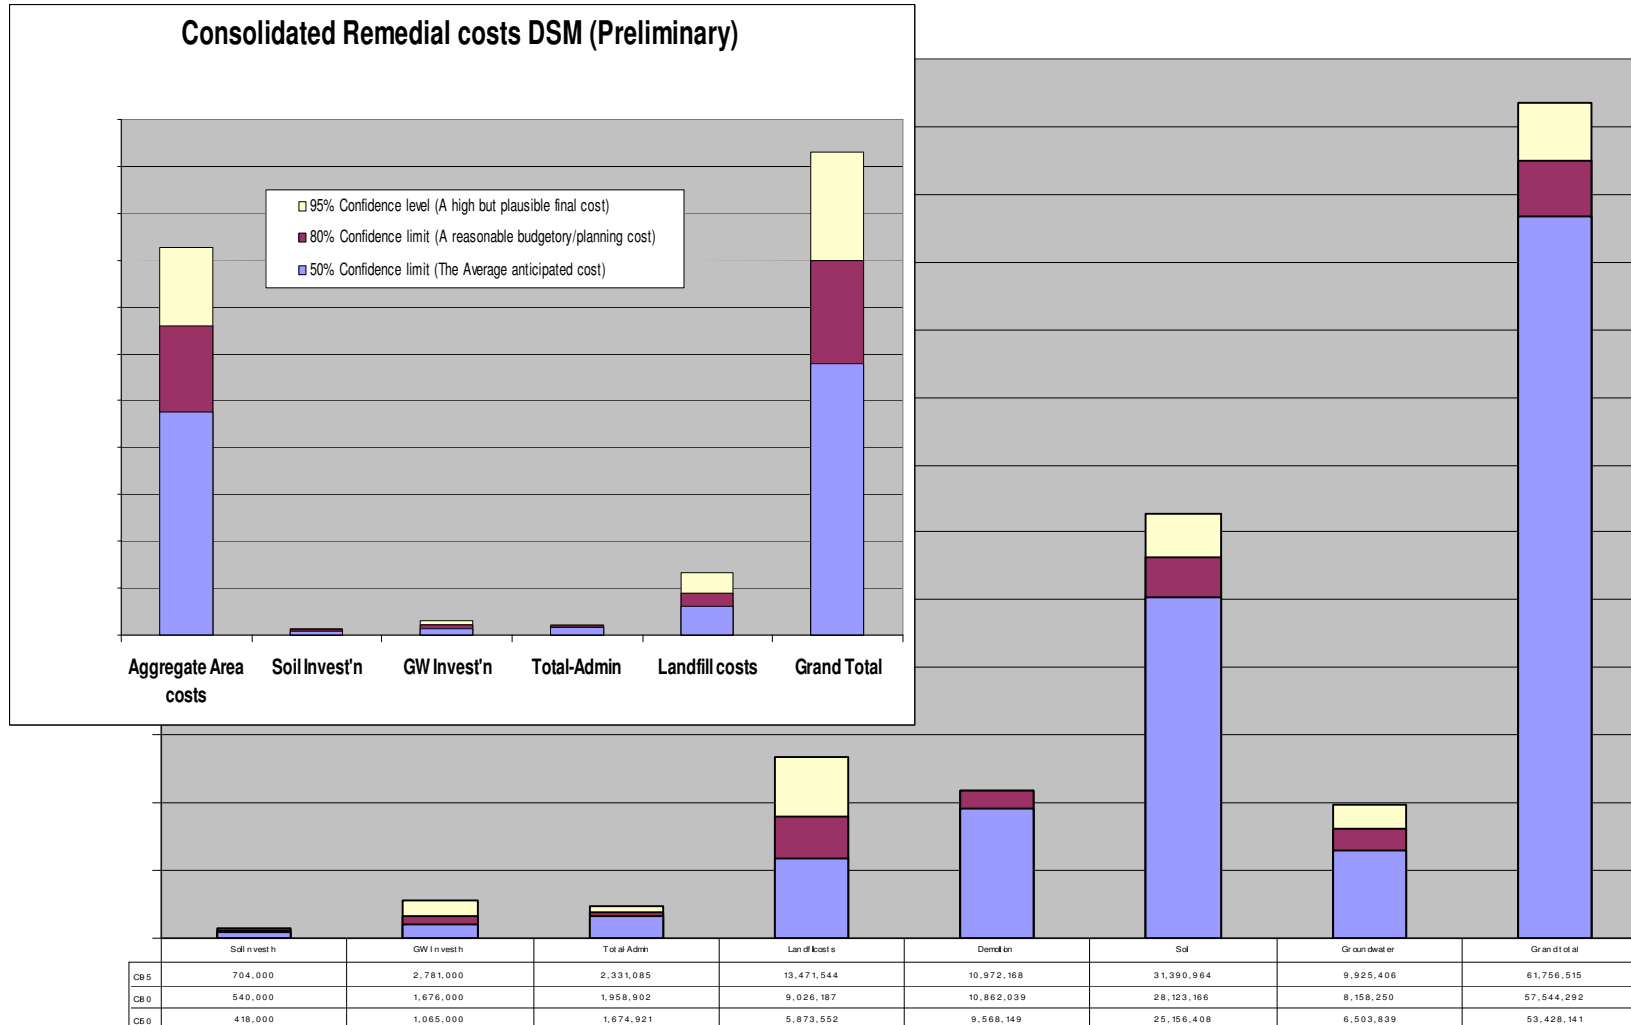

## Estimates of Soil Remediation Costs by Area - July Estimate

- 95% Confidence level (A high but plausible final cost)
- 80% Confidence limit (A reasonable budgetary/planning cost)
- 50% Confidence limit (The Average anticipated cost)

# Case Study 1 – Value of uncertainty analysis

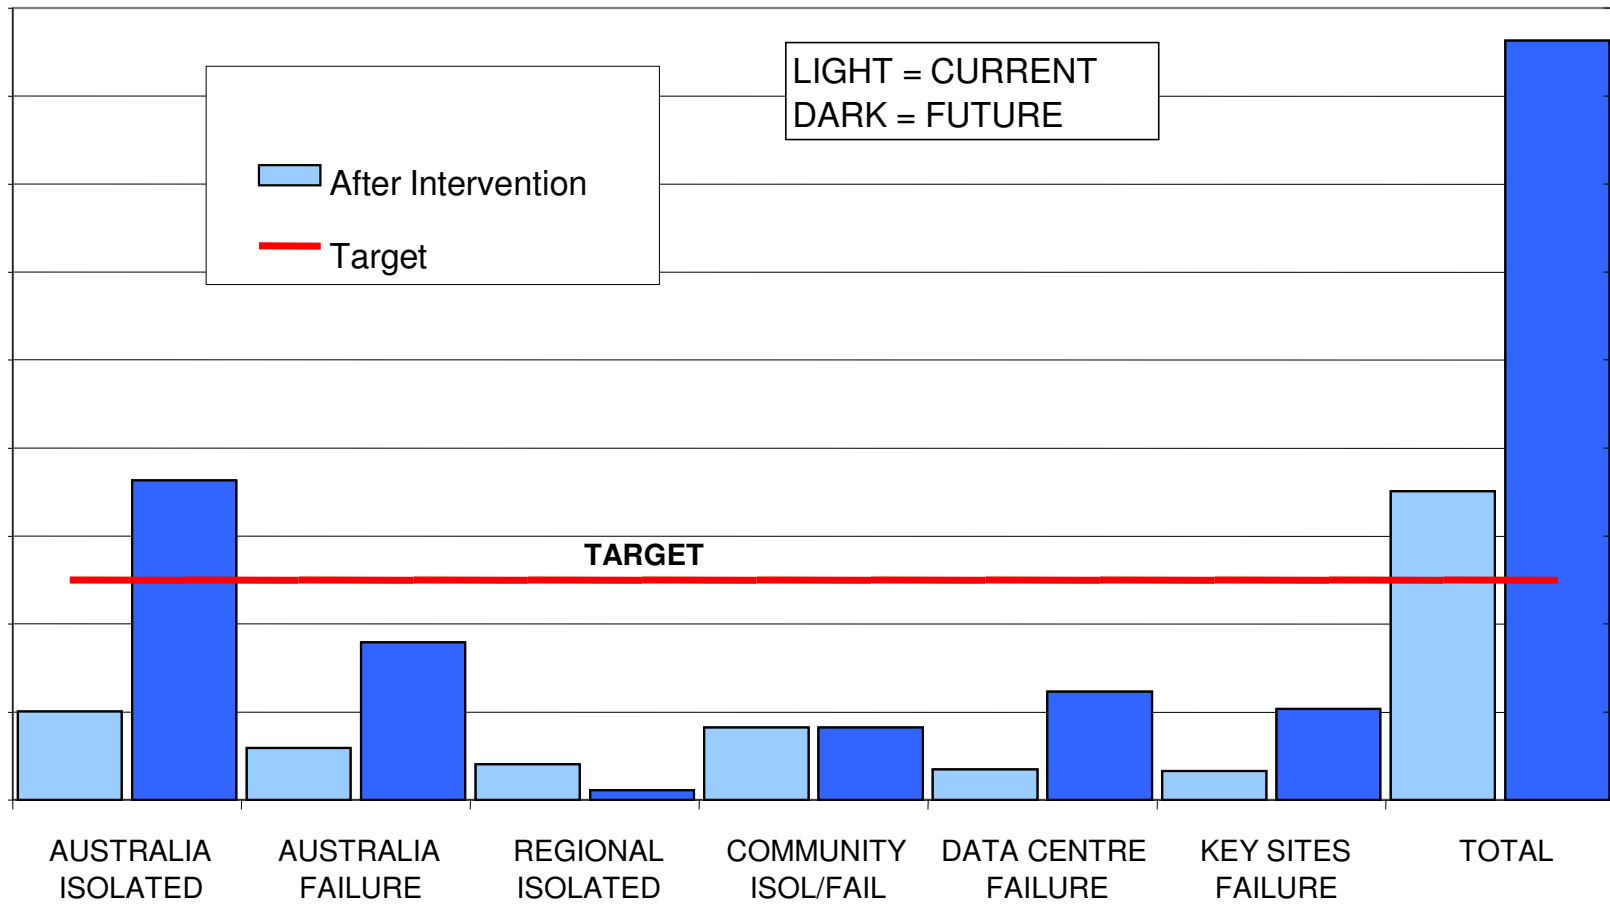

## Consolidated Remedial costs (Sept 03 revision)

# Case Study 2 – Analysis of major risks

## Original position

## Case Study 2 – Analysis of major risks

### *Action 1 - New switch (Australia Isolation)*

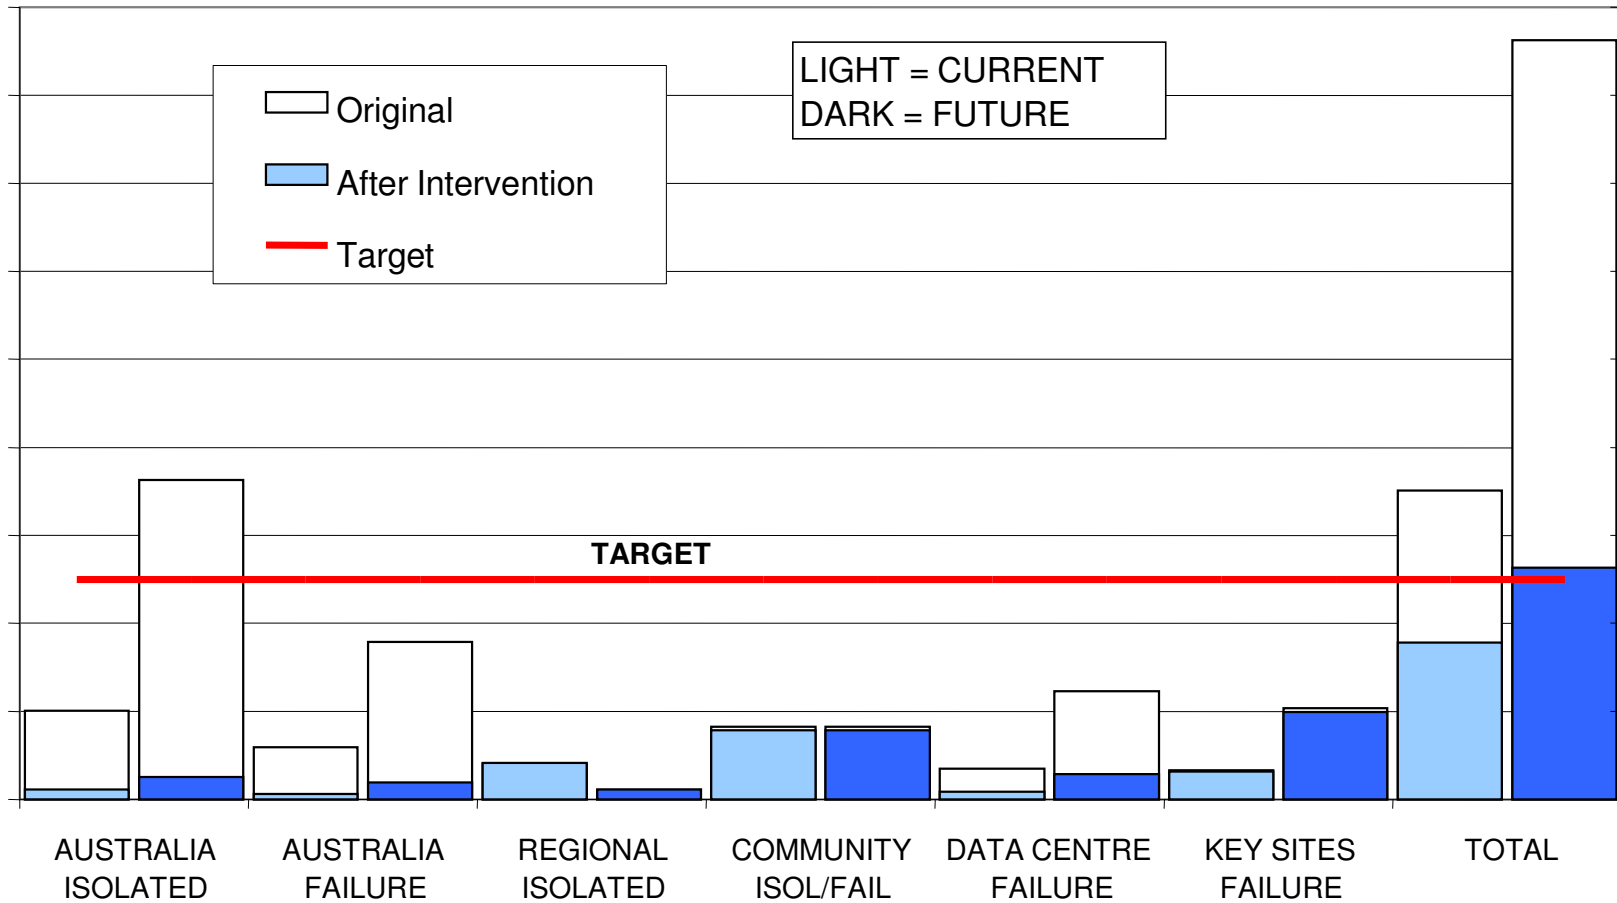

## Case Study 2 – Analysis of major risks

### *Action 2 - Disaster recovery plan for Australia Failure*

## Case Study 2 – Analysis of major risks

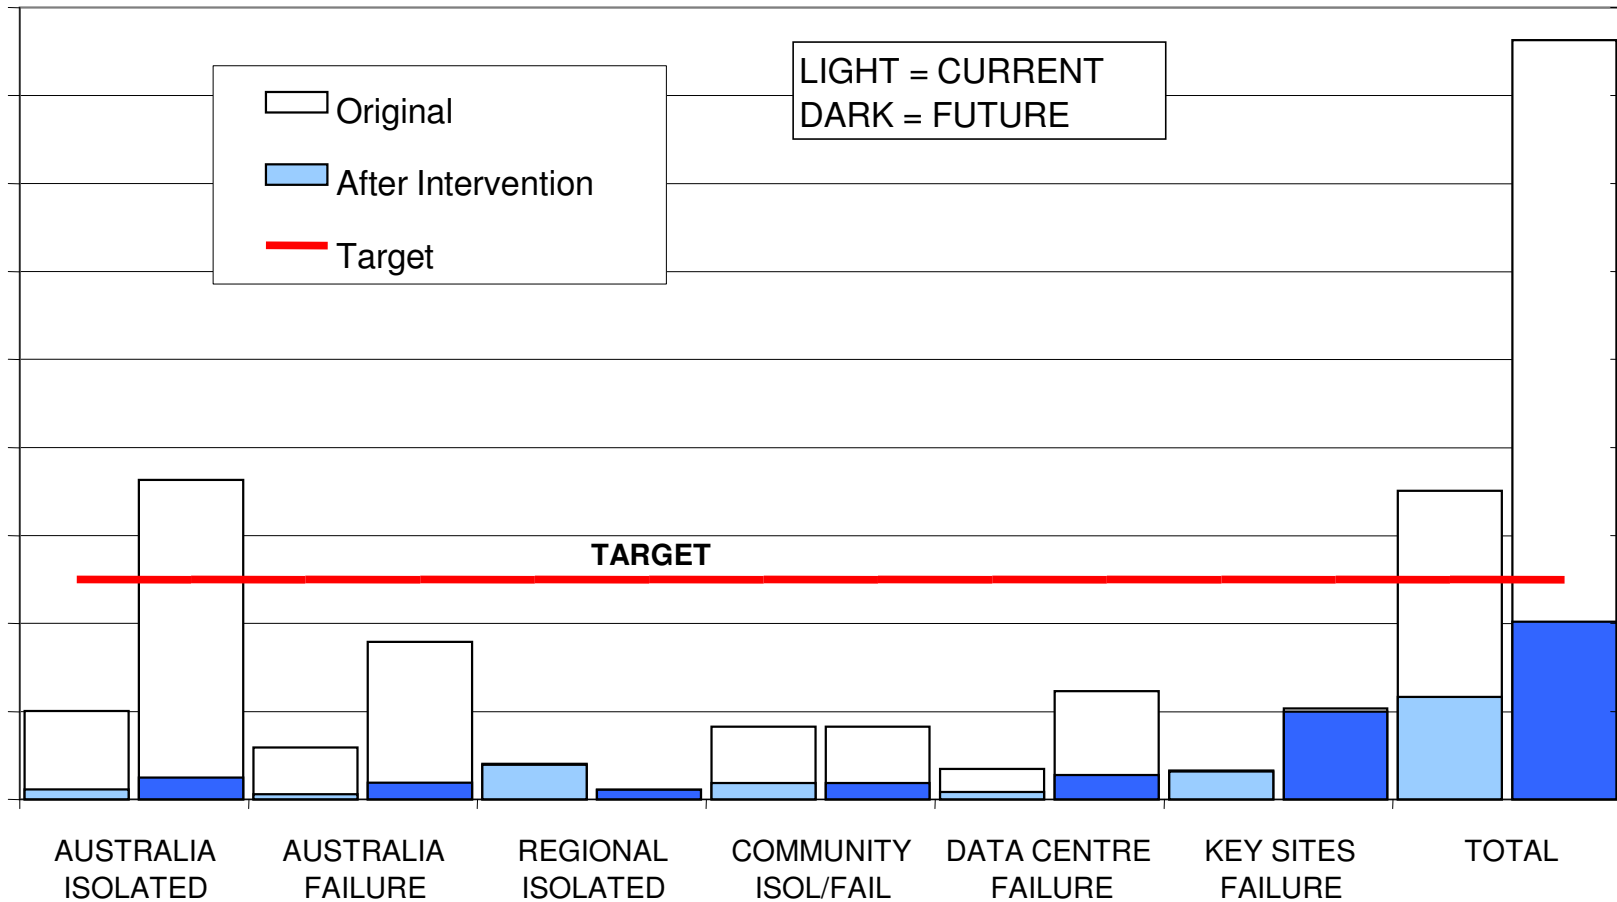

### *Action 3 - Disaster recovery plan for Data Centres*

## Case Study 2 – Analysis of major risks

### *Action 4 - Improve customer relations plus disaster response plan for Community Isolation or Failure*

# Case Study : PwC Coffee Shop

## PwC Coffee Shop : Assumption

<b>Number of coffee sold</b>	<b>45,000</b>
<b>Price per cup</b>	<b>\$2.00</b>
<b>Total revenue</b>	<b>\$90,000.00</b>
<b>Price of Coffee (per kg.)</b>	<b>\$15.00</b>
<b>Grams of coffee per cup</b>	<b>0.034</b>
<b>Other costs</b>	<b>\$50,000.00</b>
<b>Total cost</b>	<b>\$72,950.00</b>
<b>Net</b>	<b>\$17,050.00</b>
<b>Risk adjusted Net</b>	<b>\$17,050.00</b>

## PwC Coffee Shop : Assumption

### Prob.

<b>30%</b>	<b>Chance that coffee machine breaks down during the year</b>
<b>80%</b>	<b>Takes between 1 and 5 days to fix</b>
<b>24%</b>	<b>Net P</b>

	CL50	CL95	Risk <i>CL50*Net P</i>
No Coffee Sale	\$500	\$2,500	\$120
Repair cost	\$8,000	\$15,000	\$1,920
Long term loss of customers	\$100	\$300	\$24
Aggregate Risk			\$2,064
	1	0

\*connectedthinking

PRICEWATERHOUSECOOPERS 

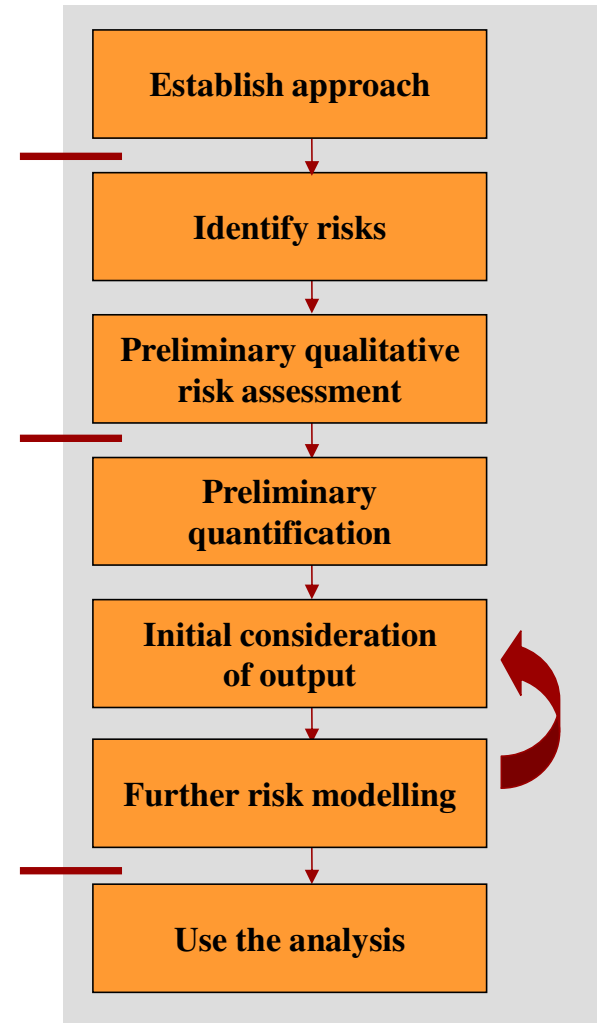

# Typical phases in the risk assessment process

**Phase 1 - Establish overall approach**

**Phase 2 - Qualitative assessment**

**Phase 3 - Gather data and model**

**Phase 4 - Use the data**

## What do we need to know ?

- What risks should be quantified ?
- What methodologies can be used to quantify risks and when is it appropriate to use each one ?
- What data should be gathered on risks and how can it be gathered
- Who should model the risks and be involved in reviewing the output ?
- What presentation techniques should be considered ?

# Summary - Acknowledging and overcoming the challenges of a qualitative approach

## The challenges

- 2 dimensional (single point) qualitative assessment of likelihood and impact can be too simple
- Practical difficulties in collecting reliable and relevant data and modelling risk
- Knowledge of risk quantification techniques is often very limited
- Gaining acceptance from business colleagues
- Risk quantification can be conceptually complex and may not be a quick fix

## Overcoming the challenges

- Understand the alternative models through training
- Be flexible
- Focus on quality of thinking
- Move towards objective measures and systematic approach
- Focus on the critical risks
- Transparent, defensible and rational decision making
- Be prepared to get dirty !

# Thank you
